GENERAL DESCRIPTION

The ADG719 is a monolithic CMOS SPDT switch. This switch is designed on a submicron process that provides low power dissipation yet gives high switching speed, low on resistance and low leakage currents.

The ADG719 can operate from a single supply range of +1.8 V to +5.5 V, making it ideal for use in battery-powered instruments and with the new generation of DACs and ADCs from Analog Devices.

Each switch of the ADG719 conducts equally well in both directions when on. The ADG719 exhibits break-before-make switching action.

Because of the advanced submicron process, –3 dB bandwidths of greater than 200 MHz can be achieved.

The ADG719 is available in a 6-lead SOT-23 package and an 8-lead μSOIC package.

PRODUCT HIGHLIGHTS

1. +1.8 V to +5.5 V Single Supply Operation. The ADG719 offers high performance, including low on resistance and fast switching times and is fully specified and guaranteed with +3 V and +5 V supply rails.

CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although the ADG719 features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

APPLICATIONS INFORMATION

The ADG719 belongs to Analog Devices' new family of CMOS switches. This series of general purpose switches have improved switching times, lower on resistance, higher bandwidths, low power consumption and low leakage currents.

ADG719 Supply Voltages

Functionality of the ADG719 extends from +1.8 V to +5.5 V single supply, which makes it ideal for battery powered instruments, where important design parameters are power efficiency and performance.

It is important to note that the supply voltage effects the input signal range, the on resistance and the switching times of the part. By taking a look at the typical performance characteristics and the specifications, the effects of the power supplies can be clearly seen.

For V_{DD} = +1.8 V operation, R_{ON} is typically 40 Ω over the temperature range.

On Response vs. Frequency

Figure 8 illustrates the parasitic components that affect the ac performance of CMOS switches (the switch is shown surrounded by a box). Additional external capacitances will further degrade some performance. These capacitances affect feedthrough, crosstalk and system bandwidth.

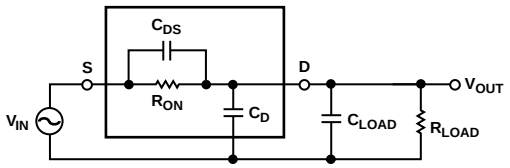

Figure 8. Switch Represented by Equivalent Parasitic Components

The transfer function that describes the equivalent diagram of the switch (Figure 8) is of the form (A)s shown below.

$$A(s) = R_T\left[\frac{s(R_{ON}\ C_{DS})+1}{s(R_T\ R_{ON}\ C_T)+1}\right]$$

where:

$R_T = R_{LOAD}/(R_{LOAD} + R_{ON})$
$C_T = C_{LOAD} + C_D + C_{DS}$

The signal transfer characteristic is dependent on the switch channel capacitance, C_{DS}. This capacitance creates a frequency zero in the numerator of the transfer function A(s). Because the switch on resistance is small, this zero usually occurs at high frequencies. The bandwidth is a function of the switch output capacitance combined with C_{DS} and the load capacitance. The frequency pole corresponding to these capacitances appears in the denominator of A(s).

The dominant effect of the output capacitance, C_D, causes the pole breakpoint frequency to occur first. Therefore, in order to maximize bandwidth a switch must have a low input and output capacitance and low on resistance. The On Response vs. Frequency plot for the ADG719 can be seen in Figure 7.

Off Isolation

Off isolation is a measure of the input signal coupled through an off switch to the switch output. The capacitance, C_{DS}, couples the input signal to the output load, when the switch is off as shown in Figure 9.

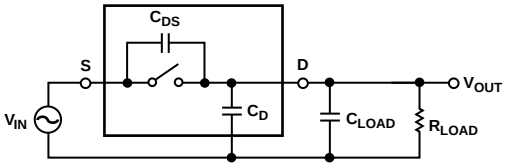

Figure 9. Off Isolation Is Affected by External Load Resistance and Capacitance

The larger the value of C_{DS}, larger values of feedthrough will be produced. The typical performance characteristic graph of Figure 5 illustrates the drop in off isolation as a function of frequency. From dc to roughly 200 kHz, the switch shows better than –95 dB isolation. Up to frequencies of 10 MHz, the off isolation remains better than –67 dB. As the frequency increases, more and more of the input signal is coupled through to the output. Off isolation can be maximized by choosing a switch with the smallest C_{DS} as possible. The values of load resistance and capacitance affect off isolation also, as they contribute to the coefficients of the poles and zeros in the transfer function of the switch when open.

$$A(s) = \left[\frac{s(R_{LOAD}\ C_{DS})}{s(R_{LOAD})\,(C_{LOAD} + C_D + C_{DS})+1}\right]$$
